Abstract

Reaction of the potassium salts of *N*-acylamido(thio)phosphates [4'-benzo-15-crown-5]NHC(S)NHP(Y)(O*i*Pr)₂ (Y = S, **HL**^I; Y = O, **HL**^{II}) with Zn(II) and Co(II) cations in aqueous EtOH leads to complexes of formulae Zn(L^{I,II} – S, Y)₂ (Y = S, **1**; Y = O, **2**) and Co(L^I – S, S')₂ (**3**), while interaction of the potassium salt of [4'-benzo-15-crown-5]C(S)NHP(O)(O*i*Pr)₂ (**HL**^{III}) with Zn(II) in the same conditions leads to a complex of composition Zn(**HL**^{III})(L^{III} – S, O)₂ (**4**).

Compounds containing two essentially different complexing groups simultaneously – a chelating fragment and a macrocycle – draw the attention of researchers as potential bimetallic catalysts [1], models at studying intracomplex redox processes [2–5] and reagents for the synthesis of supramolecular compounds [6,7].

Presence of the exocyclic functional groups in a molecule of crown-ether, interacting with atoms of a cycle or metal cations, increases complexing selectivity and complexing ability in relation to metal ions, and results in a change of the hydrophilic–hydrophobic balance and surface-active properties [8,9].

Earlier, we had reported about bis-thioureas, containing diaza-18-crown-6 and diaza-15-crown-5 [10], thiourea on the basis of monoaza-18-crown-6 [11] and thiophosphorylated thiobenzamide [12], containing a benzo-15-crown-5 cycle, possessing the ability for complexes with alkaline and transition metal cations.

Combination of crown-ether and thioacylamido(thio)phosphate fragments C(S)NHP(Y) in one molecule opens

greater opportunities for the synthesis of various supramolecular coordination compounds. Herein, we present complexes of Zn(II) and Co(II) cations (**1–4**) with ligands **HL**^{I–III} (Scheme 1) [13]. They are of doubtless interest as building blocks for creation in a molecule of combinations from crown-ethers, allowing increasing probability to form complexes with in advanced set structure.

The IR spectrum of **1** in Nujol is similar to the spectrum of **3**. The absorption bands of the P=S group of the anionic forms L^I in complexes **1** and **3** are shifted by approximately 30 cm⁻¹ to low frequencies relative to the band of the parent ligand **HL**^I. This confirms their participation in chelate formation. The absorption band of the P=O group of the L^{II} in complex **2** is also shifted to low frequencies relative to the band of the ligand **HL**^{II}, but the shift is 80 cm⁻¹. There is only one signal for the NH proton in the IR spectra of complexes **1–3** in the area 3236–3264 cm⁻¹. In the spectrum of **1–3**, there is an intense absorption band at 1508–1524 cm⁻¹ corresponding to the conjugated SCN fragment. This fact also confirms about the formation of complexes. Besides a wide intensive band of the POC group at 992–1008 cm⁻¹, in the IR spectra of **1–3** there are a set of absorption bands in the area 1098–1128 cm⁻¹, corresponding to the COC fragment. It confirms the preservation of structure of a ligand in the obtained complexes.
