## Abstract

We have studied the nuclear magnetic resonance (NMR) of  $V^{51}$  nuclei in the superconductor/ferromagnet thin film heterostructures  $Pd_{1-x}Fe_x/V/Pd_{1-x}Fe_x$  and  $Ni/V/Ni$  in the normal and superconducting state. Whereas the position and shape of the NMR line in the normal state for the trilayers is identical to that observed in a single V layer, in the superconducting state the line shape definitely changes, developing a systematic distortion of the high-field wing of the resonance line. We consider this as the first experimental evidence for the penetration of ferromagnetism into the superconducting layer, a phenomenon which has been theoretically predicted recently and dubbed the spin screening effect. © 2009 The American Physical Society.
